Plural Frege Arithmetic

Francesca Boccuni
1 Plural Grundgesetze

1 Frege’s *Grundgesetze der Arithmetik* is notoriously inconsistent. So-called Russell’s paradox arises from Frege’s Basic Law V (BLV) and the impredicative second-order comprehension axiom that accompanies it. There may be no general agreement on which one of the axioms involved in the inconsistency is the real culprit. Nevertheless, as far as Frege’s Grundgesetze are concerned, the fact of the matter is that full second- or higher-order comprehension and full Basic Law V jointly lead to inconsistency.

2 Quite recently, some fragments of Frege’s Grundgesetze were proved consistent, i.e., [Ferreira & Wehmeier 2002], [Heck 1996], [Wehmeier 1999]. Heck deploys predicative comprehension [Heck 1996], while both [Ferreira & Wehmeier 2002] and [Wehmeier 1999] adopt $\Delta_1^1$-comprehension. Their major shortcoming is that they interpret only very weak, though non-trivial, subsystems of arithmetic, like Robinson’s Q.

3 More recently, [Boccuni 2010] proposed to augment Heck’s predicative fragment of Frege’s Grundgesetze in [Heck 1996] by Boolos’ plural quantification—see e.g., [Boolos 1985]. The resulting axiomatic system, i.e., Plural Grundgesetze (PG), is shown to interpret PA$^2$.

The axioms of PG are a Plural Comprehension Principle

$$\text{PLC : } \exists x \forall x (x \equiv \phi x),$$

where $\phi x$ does not contain $xx$ free; a Predicative Comprehension Principle

$$\text{PRC : } \exists F \forall x (Fx \equiv \phi x),$$

where $\phi x$ contains neither $F$ free, nor free plural variables, nor bound second-order variables; and a schematic formulation of Basic Law V :

$$\text{V : } \{x : \phi x\} = \{x : \psi x\} \leftrightarrow \forall x (\phi x \equiv \psi x).$$

4 The restrictions on the formulae permitted in the extension-terms are exactly the same restrictions imposed on the right-hand side of PRC. By this strategy, PG, in a rather Fregean spirit, guarantees that there is a one-to-one correspondence between concepts and extensions. This, nevertheless, cripples the system to the effect that, though it recovers PA$^2$, it does not interpret Frege Arithmetic FA. This latter consists of full second-
order logic and Hume’s Principle (HP): \( \forall F, G (\#F = \#G \leftrightarrow F = G) \) which says that the number of the Fs is identical with the number of the Gs just in case F and G are equinumerous. In fact, a Fregean definition of the number operator \( \# \) in terms of extensions, which is crucial for recovering FA from BLV, requires that bound second-order variables be allowed in the scope of the extension operator. This dictates that the very definition of \( \# \) is not available in PG, let alone the derivation of so-called Frege’s Theorem, namely the derivation of appropriate formulations of second-order Peano axioms from FA. This is contested also in [Ferreira 2018] and [Hewitt 2018]. Thus, the aim of the present article is twofold: to provide a consistent extension of PG so as to recover FA, and, by that, to respond to [Ferreira 2018]’s and [Hewitt 2018]’s criticism, on the one hand; and, on the other, to highlight some interesting differences between the resulting system and [Ferreira 2018].

5 PG’s limitation can be easily overcome by restricting the formulæ allowed within extension-terms only to those not containing free plural variables. The resulting system will be shown to be consistent and capable of interpreting FA. Now, the new version of axiom \( \nu \), call it \( \nu^* \), will be schematic and such that the formulæ allowed within the abstraction operator \( \{ \} \) can contain (i) bound plural variables; (ii) both free and bound second-order variables; (iii) but no free plural variables at all. Call the resulting system \( V^\text{imp} \) since impredicative second-order formulæ are allowed in extension-terms. Also, \( V^\text{imp} \) preserves PG’s axioms PLC and PRC, restricted as above. From this, it should be clear that [Boccuni 2010]’s PG and [Ferreira 2018]’s PE are subsystems of \( V^\text{imp} \).

6 The main aim of the present article is merely technical. On the one hand, it will be proved that one of the restrictions imposed on PG’s \( \nu \) and, other things being equal, on PE’s BLV and predicative comprehension can be consistently lifted. On the other, it will be proved that FA can be interpreted in the resulting system. Nevertheless, it is interesting to mention a philosophical issue. There might be several desiderata a Fregean foundation of arithmetic based on BLV might be expected to satisfy—consistency being an obvious pre-requisite. These might be, possibly among others: the preservation of a one-to-one correspondence between concepts and extensions; the interpretation of full second-order arithmetic; the interpretation of full second-order arithmetic on the basis of Frege’s definitions of the mathematical notions necessary to prove Frege’s Theorem. As said, in PG the one-to-one correspondence between concepts and extensions is preserved. Furthermore, PG has enough mathematical strength to interpret full \( PA^2 \), in which natural numbers are defined à la Zermelo on the basis of the empty extension \( \{ x : x \neq x \} \) and the singleton operation. On the other hand, by lifting the restriction concerning bound second-order variables in \( \nu^* \), \( V^\text{imp} \) loses the one-to-one correspondence between concepts and extensions. The up-side is that, unlike PG, \( V^\text{imp} \) recovers \( PA^2 \) via FA, i.e., by a Fregean definition of the number operator \( \# \) and by deriving a formulation of HP from \( \nu^* \)—which cannot be done in PG. With respect to the aforementioned desiderata, each approach has nice advantages and clear shortcomings. So, depending on which among the above desiderata is more fundamental, if any, one might prefer PG over \( V^\text{imp} \) or the other way around. I am not going to take a stand on this here. But it is worth mentioning that a case can be made in favour of PG over \( V^\text{imp} \), if the one-to-one correspondence between concepts and extensions is deemed crucial, and one rests content with any derivation of second-order Peano axioms. On the other hand, \( V^\text{imp} \) or PE would be preferable over PG, if \( PA^2 \) were to be recovered in a way as
faithful as possible to Frege’s, while at the same time the one-to-one correspondence between concepts and extensions were not deemed essential to a Fregean foundation of arithmetic.\textsuperscript{10}

2 Consistency

Being \(V_{\text{imp}}\) an extension of \(PG\) and \(PE\) in which one or more restrictions on the axioms are lifted, and being both \(PG\) and \(PE\) consistent [see Boccuni 2011, Ferreira 2018], the first worry to address concerns the consistency of \(V_{\text{imp}}\). The consistency result in what follows, then, is the main result of this article. As a matter of convenience, I will rely on \(PG\)’s consistency proof, which implies the consistency of the fragment of \(V_{\text{imp}}\) that is equivalent with \(PG\). This fragment consists of all instances of \(V^{*}\) not containing bound second-order variables, all instances of \(PRC\) since the restrictions imposed by [Boccuni 2010] are the same imposed on \(PRC\) in \(V_{\text{imp}}\), and all instances of \(PLC\) not containing extension-terms containing bound second-order variables. What we need to prove is that: (i) all instances of \(V^{*}\) containing bound second-order variables hold—i.e., the extension-terms introduced by those instances have denotations; (ii) and all instances of \(PLC\) containing extension-terms with bound second-order variables hold.\textsuperscript{11}

On the basis of this result, the overall strategy will be:

1. to recap the consistency proof of \(PG\)—i.e., of the aforementioned fragment of \(V_{\text{imp}}\);  
2. to prove that all extension-terms containing bound second-order variables have denotations;  
3. to prove that all instances of \(V^{*}\) containing extension-terms with bound second-order variables hold in the model;  
4. to prove that all instances of \(PLC\) containing extension-terms containing bound second-order variables hold in the model.

2.1 The consistency of \(PG\)’s twin theory

Let us consider the fragment of \(V_{\text{imp}}\) that is equivalent with \(PG\). The model of \(PG\) in [Boccuni 2011] will also be a model for such a fragment:

1. First, [Boccuni 2011] fixes the first-order domain, namely \(\omega\), and the domain for plural variables, namely \(\omega\); and provides denotations for the extension-terms not containing second-order variables at all, but possibly containing bound plural variables, in § 4.1 and § 4.1.1. In line with [Heck 1996], this is accomplished by the definition of a function \(f^{2}(m,n)\) as \(2j(m,n)\), where \(j(m,n)\) is a pairing function assigning a natural number to each ordered pair of natural numbers \((m,n)\). Recall that free plural variables are not allowed in extension-terms both in \(PG\) and in \(V_{\text{imp}}\).\textsuperscript{12}  
2. Secondly, [Boccuni 2011, § 4.2] fixes the domain for the second-order variables, namely a set \(\pi(\omega)\) containing all subsets of the first-order domain whose defining formula contains no free variables of any kind nor bound second-order variables (it may contain bound plural variables).  
3. Thirdly, [Boccuni 2011, § 4.2.1] provides denotations for extension-terms containing free second-order variables in line with [Heck 1996, § 3.2].  
4. Then, [Boccuni 2011, § 4.3] shows that all instances of \(BLV\) containing no bound second-order variables hold in this model—the same holds for all instances of \(V^{*}\) containing no bound second-order variables.
5. Then, [Boccuni 2011, § 4.4] shows that all instances of PLC hold in this model.

6. Finally, [Boccuni 2011, § 4.5] shows that all instances PLC hold in this model.

This model is also a model for the fragment of \( v_{imp} \) corresponding to PG. We need to extend this interpretation so that all instances of \( v^* \) containing extension-terms with bound second-order variables hold—i.e., the corresponding extension-terms have denotations; and all instances of PLC containing these latter extension-terms hold—still, as a matter of convenience I will prove that PLC holds.

### 2.2 Extension-terms containing bound second-order variables

This section closely follows [Heck 1996, § 3.4]. Let an interpretation \( I \) be as above, i.e., the domains for first-, second-, and plural variables are \( \omega, \mathbb{N}(\omega), (\omega) \), respectively.

Let the degree of an extension-term \( \{ x : Ax \} \) be 0 if, and only if, \( Ax \) is a formula of the language of \( v_{imp} \) containing no bound second-order variables at all. It is of degree 1 if, and only if, it does, but it contains no extension-terms containing bound second-order variables. In general, an extension-term \( \{ x : Ax \} \) is of degree \( n \) if, and only if, the greatest degree of any extension-term contained in it is \( n - 1 \).

Let us arrange the extension-terms by degree in an \( \omega \times \omega \)-sequence, where the extension-terms of each degree form an \( \omega \)-sequence and, for each extension-term \( t \), each term preceding it is of degree less than or equal to that of \( t \) itself. Let \( K(m,n) \) be a function defined as \( 4^j(m,n) + 1 \), where \( j(m,n) \) is as above. Previously, the consistency proof for the fragment of \( v_{imp} \) corresponding to PG has assigned denotations to all extension-terms of degree 0. Let us assume we have done the same for all terms preceding a term \( t = \{ x : Ax \} \) of degree greater than 0, and let us assume that, for any extension-terms \( \{ x : Bx \} \) and \( \{ x : Cx \} \) preceding \( t \) in the sequence, those terms have the same denotation just in case \( Bx \) and \( Cx \) are equivalent under \( I \) with respect to \( x \). We assign to \( t \), its denotation, that of any preceding term \( \{ x : Dx \} \) such that \( Dx \) is equivalent to \( Ax \) under \( I \) with respect to \( x \), if there is such a term; if there is no such term, we assign to \( t \) as its denotation \( K(m,n) \), where \( m \) is the rank of \( t \), \( n \) is the degree of \( t \), and, for all \( k < n, K(m,k) \) has already been assigned as denotation to some extension-term, but \( K(m,n) \) has not.

Check now that, if \( \{ x : Bx \} \) and \( \{ x : Cx \} \) precede or are identical with \( t \), then \( Bx \) and \( Cx \) are equivalent under \( I \) with respect to \( x \) if, and only if, \( \{ x : Bx \} \) and \( \{ x : Cx \} \) have been assigned the same denotation. The case in which \( \{ x : Bx \} \) and \( \{ x : Cx \} \) precede \( t \) in the sequence is covered by the previous assumption. Now, let \( t = \{ x : Bx \} \). Since \( t \) is \( \{ x : Ax \} \) by previous assumption, the denotations of the terms \( \{ x : Ax \} \) and \( \{ x : Bx \} \) are identical. Then, \( Ax \) and \( Cx \) are equivalent if, and only if, \( \{ x : Ax \} \) and \( \{ x : Cx \} \) have been assigned the same denotation by construction via the function \( K(m,n) \).

### 2.3 All instances of \( v^* \) containing bound second-order variables are true in this model

This section closely follows [Boccuni 2011, § 4.3], and [Heck 1996, § 3.5].

**Theorem 1.** Every instance of \( v^* \) containing bound second-order variables holds in this model.

**Proof.** \( v^* : \{ x : \varphi x \} = \{ x : \psi x \} \iff \forall x (\varphi x \leftrightarrow \psi x) \),

where \( \varphi \) and \( \psi \) are restricted as above.\(^{11} \)
Let \( \{x : Ax\} \) and \( \{x : Bx\} \) be extension-terms, such that \( Ax \) is equivalent to \( \varphi x \) and \( Bx \) is equivalent to \( \psi x \). Let us assign the denotations of \( \{x : Ax\} \) and \( \{x : Bx\} \) respectively to \( \{x : \varphi x\} \) and \( \{x : \psi x\} \) as their denotations. From the previous section, in the \( \omega \times \omega \)-sequence either \( \{x : Ax\} \) is prior to \( \{x : Bx\} \), or conversely. Suppose \( \{x : Ax\} \) precedes \( \{x : Bx\} \), then they have the same denotation just in case \( Ax \leftrightarrow Bx \) under \( I \) with respect to \( x \). So, if \( Ax \leftrightarrow Bx \), then \( \varphi x \leftrightarrow \psi x \) as well. Finally, the right-hand side of \( V^* \), \( \forall x(\varphi x \leftrightarrow \psi x) \), is true just in case \( \varphi x \) and \( \psi x \) are equivalent. □

Given that also all instances of PLC are true in this model, since plural variables vary over the full power set of \( \omega \), from the previous constructions it follows that \( V_{\text{imp}} \) is consistent.

### 3 Frege Arithmetic and Frege’s Theorem

The aim of this section is twofold. First, we need to prove that Frege Arithmetic \( \mathsf{FA} \) can be interpreted in \( V_{\text{imp}} \); secondly, that Frege’s Theorem is implied by \( V_{\text{imp}} \). Both goals can be easily achieved. As mentioned earlier, [Ferreira 2018]’s \( \mathsf{PE} \) is a subsystem of \( V_{\text{imp}} \). Since \( \mathsf{PE} \) interprets \( \mathsf{FA} \) and derives Frege’s Theorem, so does \( V_{\text{imp}} \).

Still, there are two issues worth investigating. First, it is instructive to see how \( V_{\text{imp}} \) recovers \( \mathsf{FA} \), given the balance between plural and second-order resources in order to retain consistency. Secondly, the derivation of Frege’s Theorem in \( V_{\text{imp}} \) relies on the Weak Reducibility Theorem by [Ferreira 2018], which is crucial to prove the Successor Axiom in \( \mathsf{PE} \) and \( V_{\text{imp}} \). The recovery of \( \mathsf{FA} \) will be investigated in § 3.1. In § 3.2, the Successor Axiom will be derived, in order to make clear where weak reducibility is at work and why it is necessary, and highlight some differences with [Ferreira 2018]; whereas, for the sake of brevity, all other Peano axioms will not be derived, since they follow in \( \mathsf{PE} \) and therefore in \( V_{\text{imp}} \).

#### 3.1 \( \mathsf{FA} \)

First of all, it has to be shown that an axiomatic formulation of \( \mathsf{HP} \), i.e., \( \#F = \#G \leftrightarrow F = G \), is a theorem of \( V_{\text{imp}} \). As a matter of fact, in [Heck 1996] \( \mathsf{HP} \) follows in a predicative system for Frege’s BLV. Since [Heck 1996] is a subsystem of \( V_{\text{imp}} \), \( \mathsf{HP} \) follows also in this latter theory.

In a standard Fregean setting with extension-terms, the definitions of the equinumerosity relation \( \approx \) and of the number operator \( # \) require second-orderly impredicative resources. Also other notions necessary for recovering \( \mathsf{FA} \) require such resources: i.e., \( \text{predecessor}, \text{ancestral} \), and the concept of \( \text{natural number} \).

In \( V_{\text{imp}} \) the delicate balance between plural and second-order resources, mirrored by the restrictions on the axioms, requires that some definitions are provided in terms of second-order quantification, while others are defined in terms of plural quantification. This has to be done, because, on the one hand, free plural variables are not allowed in the scope of the extension operator: so, for instance, \( # \) cannot be defined by plural resources, since this would require allowing for plural parameters within extension-terms. On the other hand, second-orderly definitions in \( V_{\text{imp}} \) are restricted to \( \mathsf{PRC} \)-definable concepts and relations. Suppose we define \( = \) in terms of an existentially quantified second-order formula \( \exists R \ldots \) as it is usually done. That would be a formula...
indeed allowed in extension-terms in \( V_{imp} \), but at the same time the relations quantified over would be, on the basis of the restrictions imposed on \( PRC \), only the predicatedly definable ones, so the definition of \( * \) would not involve the class of all bijections, but only the class of predicative bijections. But if equinumerosity is defined in terms of plural quantification, then the equinumerosity notion can be defined in terms of all pluralities, since \( PLC \) has no restrictions at all: \(^{19} \) for any formulæ \( \varphi, \psi \) of the language of \( V_{imp} \).

**Definition 1 (\( \sim \))**

\[ \varphi \sim \psi : = \exists \, xx(\forall \, y(\varphi(y) \rightarrow \exists lx(\psi(x) \land (x,y) \land xx)) \land \forall y(\psi(y) \rightarrow \exists lx(\varphi(x) \land (y,x) \land xx))) \]

Also, for any second-order variable \( F \), the \#-operator is defined as follows:

**Definition 2 (\#)**

\[ \#F : = \{ x : \exists \, G(x = \{ y : Gy \} \land G \equiv F) \}. \]

From the definitions provided so far, the axiomatic formulation of \( HP \) from above follows in \( V_{imp} \).

The other three fundamental notions to recover \( FA \) are the notions of zero, predecessor, and natural number. The first one is straightforward, since it utilises a valid instance of \( PRC \), i.e., \( \exists \forall x(Fx \leftrightarrow x \neq x) \). Call this concept \( \text{Empty} \), and provide the definition of zero: \( 0 := \#\text{Empty} \).

Since \( PRC \) alone, due to the restrictions concerning bound second-order variables, cannot define the notions of predecessor, ancestral and natural number because of their irreducible impredicativity, \( PLC \) will have to do the job. In what follows, I will focus on the first and the third.

The notion of predecessor, provided by a valid instance of \( PLC \), is given in terms of pluralities and \#-terms: \(^{20} \)

**Definition 3 (Predecessor)**

\[ x \text{ precedes } y; (x,y) \quad \text{pp} \equiv \exists f \exists u (fu \land y = \#f \land x = \#(x.fz \land z \neq u)) \]

In order to move on to the definition of natural number, also the definitions of hereditary, ancestral, and weak ancestral are needed. Those are easily obtained by plural quantification. In particular, Hereditary: The plurality \( ss \) is hereditary in the plurality \( rr \). By this: \( \forall x.\, \text{Her}(ss,rr) : = \forall xy ((x,y) \land rr \rightarrow (x \land ss \rightarrow y \land ss)) \); Ancestral: \( x \) comes before \( y \) in the \( rr \)-series: \( (x,y) \quad \text{rr}^* : = \forall ss(\forall x (x,z) \land rr \rightarrow z \land ss) \land \text{Her}(ss,rr) \rightarrow y \land ss) \); Weak Ancestral: \( (x,y) \quad \text{rr}^* : = (x,y) \land \text{rr}^* \land x = y \).

Finally, the notion of natural number is defined by a valid instance of \( PLC \) in terms of the weak ancestral \( pp^* \) of the predecessor:

**Definition 4 (\( \mathbb{N} \))**

\[ x \quad \mathbb{N} : = (0,x) \quad \text{pp}^* \]

### 3.2 Frege’s Theorem

The above definitions are sufficient for deriving Frege’s Theorem, namely a derivation of second-order Peano axioms in \( V_{imp} \) that mirrors Frege’s. Of course, in \( V_{imp} \) second-order Peano axioms are proved in the following plural formulations:

\[(PA1) \quad 0 \quad \mathbb{N} \]
\[(PA2) \quad \forall xy(x \quad \mathbb{N} \land (x,y) \quad \text{pp} \rightarrow y \quad \mathbb{N}). \]
\[(PA3) \quad \forall xy(x \quad \mathbb{N} \land y \quad \mathbb{N} \land z \quad \mathbb{N} \land (x,y) \quad \text{pp} \land (x,z) \quad \text{pp} \rightarrow y = z) \]
\[(PA4) \quad \forall xy,z(x \quad \mathbb{N} \land y \quad \mathbb{N} \land z \quad \mathbb{N} \land (x,z) \quad \text{pp} \land (y,z) \quad \text{pp} \rightarrow x = y) \]
\[(PA5) \quad \exists x (x \quad \mathbb{N} \land (x,0) \quad \text{pp}) \]
\[(PA6) \quad \forall x (x \quad \mathbb{N} \rightarrow \exists y (y \quad \mathbb{N} \land (x,y) \quad \text{pp})). \]
(PA7) \( \forall x \, (x \cdot x \land \text{Her}(xx,pp) \rightarrow \forall x (x \cdot \mathbb{N} \rightarrow x \cdot xx)) \).  

As mentioned, in what follows, I will focus only on PA6, since in PA6 the application of [Ferreira 2018]’s weak reducibility comes into play.

Theorem 2. PA6. The Successor Axiom: \( \forall x (x \cdot \mathbb{N} \rightarrow \exists y (y \cdot \mathbb{N} \land (x'y) \cdot pp)) \).

A standard strategy to prove the Successor Axiom in FA requires the proof of the so-called Lemma on Successors, i.e., \( \forall x (\#(x,x)) \cdot pp \), which states that every number \( x \) precedes the number of the individuals \( z \) in the weak predecessor-series ending with \( x \). Still, the existence of numbers is delivered by HP. This latter is restricted to PRC-definable concepts, to the effect that the supposed \#-term “\( \#(x,x) \cdot pp \)” is impermissible by the definition of \# and by PRC. Thus, in \( v_{\text{imp}} \cdot HP \) cannot prove the existence of the number \( \#(x,x) \cdot pp \), since the term “\( \#(x,x) \cdot pp \)” , on the basis of the definition of the notion of predecessor \( pp \), contains bound second-order variables and thus is \( v_{\text{imp}} \)-impermissible—see Definition 3.

Still, [Ferreira 2018]’s \( PE \) implies a Weak Reducibility Theorem, stating that, if \( x \) is a natural number, there is a (predicative) concept that is co-extensive with the formula \( y \cdot x \cdot x = y \cdot x \cdot x \), where \( x \) is defined impredicatively. The Weak Reducibility Theorem, in turn, is implied by a Finite Reducibility Theorem. In \( PE \), it is indeed the Weak Reducibility Theorem that underlies the proof of the Successor Axiom. And that is also what will be used in \( v_{\text{imp}} \).

Proof. By Mathematical Induction.

First of all, for the sake of convenience but without loss of generality, let us define:

Definition 5 (\( \text{ss} \ assaulted) \, x \cdot y \Rightarrow x \cdot \mathbb{N} \cdot y \cdot (x'y) \cdot pp \).

We can then show by induction that every natural number \( x \) precedes the number of the plurality \( z \cdot x \), by the plural analogue of what Zalta calls the Lemma on Successors [see Zalta 2017]:

Lemma 1 (Lemma on Successors). \( \forall x ((x',\#(z,x)) \cdot pp) \).

Since \( x \) and \( z \) are natural numbers by the definition of \( \text{ss} \) , by weak reducibility the formula \( z \cdot x \) is co-extensive with a PRC-definable concept, which is HP-permissible. We can then prove the Lemma on Successors by induction. Consider the condition \( (y',\#(z,x)) \cdot pp \) contained in the Lemma. This condition can be stated by PCL, and defines the plurality containing ordered pairs whose first member is a natural number \( y \) that precedes the number of the plurality defined by the condition “\( z \cdot x \cdot y \)”. By plugging that condition in the right-hand side of PCL, we get a further plurality, call it \( qq \), containing all individuals \( y \) that satisfy the condition \( (y',\#(z,x)) \cdot pp \) (i.e., \( y \cdot \text{being in the plurality of predecessors of the number of all individuals } z \text{ such that } z \cdot x \cdot y \) ). The strategy is to instantiate the plurality \( xx \) in the principle of mathematical induction by \( qq : 0 \cdot qq \cdot \text{Her}(qq,\mathbb{N}) \rightarrow \forall x (x \cdot qq) \).

Since the consequent is the reconfigured Lemma on Successors, we can prove this Lemma by proving both that \( 0 \cdot qq \) and that \( qq \) is hereditary on \( \mathbb{N} \) [see Heck 2012, § 6.6.]:

Theorem 3. Inductive Base: \( 0 \cdot qq \).

Proof. From PA5 and the fact that, for any plurality \( xx \cdot (x'y) \cdot xx \cdot \exists z ((z,y) \cdot xx) \), which by substitution implies \( (x,0) \cdot pp \rightarrow \exists z ((z,0) \cdot pp) \), it follows that \( (x,0) \cdot pp' \).

By definition of \( pp' \), \( (x,0) \cdot pp' \), \( x = 0 \), which by \( (x,0) \cdot pp' \) implies that \( x = 0 \). Thus, 0 is the only member of the plurality \( (x,0) \cdot pp' \).

By these two latter and PA1, it follows that \( x \cdot \mathbb{N} \land x = 0 \cdot \mathbb{N} \land (x,0) \cdot pp' \), which, by definition of \( \text{ss} \), implies \( x = 0 \). Thus, by weak reducibility and HP, \( \#(x,x) = 0 \) exists. By the Lemma Concerning Zero and \( \exists x (x = 0) \) it follows that \( \#(x,x) = 0 \), which by
substitution implies that $x \neq 0$. By $x \neq 0$, $x \neq 0$, weak reducibility, and \textit{hp}, it follows that \#[$x; x = 0 \land x \neq 0$] exists. But such a number is 0 itself, since there is no $x$ such that $x$ is less than or equal to 0 and $x \neq 0$, by definition of $<$, $(x, 0) \neq$ from above, and the Lemma Concerning Zero. By $x \neq 0$, the existence of \#[$x; x = 0$], and \#[$x; x = 0 \land x \neq 0$] = 0, it follows that $x \neq 0 \land x = \#[$x; $x = 0$] \land \#[$x; x = 0 \land x \neq 0$] = 0, which implies, by definition of \textit{pp}, that $(0, \#[$x; $x = 0$]) \neq$ $pp$, i.e., 0 $qq$. □

Theorem 4 Inductive Step: $qq$ is hereditary on $\mathbb{N}$.

Proof. In order to prove the inductive step, we need to prove $(y, \#[$$z; z \leq y$])$ $pp$ by assuming that (1) $(x, y)$ \textit{pp}, and (2) $(x, \#[$$z; z \leq x$])$ $pp$, for any natural numbers $x, y$. In particular, by the definition of $pp$, we have to show that, for some concept $F$, there is a $u$ such that (a) $Fu$; (b) $\#[$$z; z \leq y$]$ = \#[$$z; z \leq x$]; (c) $y = \#[$$z; z \leq x$] \land$ $z \neq u$. Let us assume that $F$ is $z \leq y$, by weak reducibility, and $u \neq y$. So (a) becomes (a') $y \leq y$, which holds, since by its definition, $<$ is reflexive; (b) becomes (b') $\#[$$z; z \leq y$]$ = \#[$$z; z \leq x$] which is true since it is an instance of the identity principle; (c) becomes (c') $y = \#[$$z; z \leq y \land z \neq y$].

By assumptions (1) and (2), and by PA3, it follows that $y = \#[$$z; z \leq x$], which by (c') becomes $\#[$$z; z \leq y \land z \neq y$]$ = \#[$$z; z \leq x$]. This latter claim is what we have to prove. This can be done by the Lemma on the Weak Predecessor, i.e., $x \in \mathbb{N}$, $(x, y)$ $pp$, and $\#[$$z; z \leq y$]$ = \#[$$z; z \leq x$], from which, since $x$ and $y$ are natural numbers and by the definition of $<$, it follows that $y \in \mathbb{N}$, $(x, y)$ $pp$, and $\#[$$z; z \leq y$]$ = \#[$$z; z \leq x$] $\land$ $z \neq y$, where the consequent is what we had to show in the first place. □

31 Given the inductive proof of the Lemma on Successors and the proof of PA, PA6 follows. □

32 \textit{PE} recovers \textit{FA} via a predicative notion of equinumerosity, i.e., $F = G := \exists y (\forall x (Fy \rightarrow \exists ! x \in x \land Fx \land y = \#[x; x < y])))$. In \textit{PE}, this is not a matter of choice, since otherwise the very definition of the cardinality operator would be blocked on the basis of the ban on impredicative variables in \textit{PE}'s \textit{BLV} [see Ferreira 2018, §4]. Mathematically, this is not a severe issue, since impredicative bijections will be finite, as soon as they are restricted to finite concepts $F$ and $G$, and thus co-extensive with predicative ones by finite reducibility. Still, it shows that in \textit{PE} the import of finite reducibility is more pervasive than in $\textit{V}_{\text{imp}}$. All in all, what $\textit{V}_{\text{imp}}$ really needs is only a way to prove the Successor Axiom, and that is achieved by a weaker result than finite reducibility, namely by weak reducibility; whereas, without finite reducibility, \textit{PE} would not even start to recover \textit{FA} for the just aforementioned reason. Unlike $\textit{V}_{\text{imp}}$, where the definition of the cardinality operator takes advantage of the (plural) impredicative definition of equinumerosity, \textit{PE} requires finite reducibility to correct a limitation the axioms suffer from because of the restrictions imposed on them. But, as shown in this article, some of those restrictions are unnecessary, so there is no apparent reason for banning impredicative bijections from the definition of the cardinality operator.

33 Furthermore, \textit{PE} and $\textit{V}_{\text{imp}}$ are on a par as long as finite cardinals are concerned. As long as one agrees with [Ferreira 2018] that so far no satisfactory set theory has been based on consistent fragments of \textit{BLV} and likely there will never be one, the fact that by \textit{BLV} we cannot move up from the finite into the transfinite should not be troublesome at all. But some may be disappointed that we should stop at PA2, especially since some fragments of ZFC have been interpreted in consistent fragments of \textit{BLV}. At the very least, it would be nice to leave the possibility open. To this extent, upon further investigation, $\textit{V}_{\text{imp}}$ might prove useful for the purpose of going beyond PA2. After all, in $\textit{V}_{\text{imp}}$, unlike \textit{PE}, the extension containing all natural numbers \{xx $\in \mathbb{N}$\} is delivered by $\textit{V}^*$. It might be worrisome that, once the definition of $\mathbb{N}$ is unravelled, its extension-
term seems to contain a free plural variable, namely $pp'$. Still, this is not problematic: in fact, every single instance of $pp'$ can be substituted by its defining formula, which contains no free plural variables at all, as it is clear once the definition of $pp'$ is unfolded:

$$x \prec \mathbb{N} := (0, x) \quad pp' := 0 = x \lor (0, x) \quad pp := 0 = x \lor (0, x) \lor (0, Fz \land z \neq u) \rightarrow y \lor xx \land \text{Her}(xx, 3 \exists u (Fu \land x = #F \land 0 = #)]z.Fz \land z \neq u) \rightarrow x \lor xx).$$

The more liberal restrictions imposed on $\text{V}_{\text{imp}}$’s axioms than the restrictions imposed on $\text{PE}$’s axioms might be used as a basis to extend $\text{V}_{\text{imp}}$ to a theory of infinite extensions aimed at recovering larger fragments of set theory.\(^{34}\)

### 4 Closing remarks

In [Boccuni 2010], the system $\text{PG}$ is presented, which recovers $\text{PA}^2$. Due to the predicative restriction both on the second-order comprehension axiom $\text{PRC}$ and on axiom $\text{V}$, $\text{PG}$ cannot interpret Frege Arithmetic $\text{FA}$. Consequently, $\text{PG}$ cannot prove Frege’s Theorem, and thus $\text{PA}^2$, though interpretable in $\text{PG}$, cannot be recovered in a way that resembles Frege’s. In this paper, it is shown that the predicative restriction on axiom $\text{V}$ can be lifted. By consistently extending axiom $\text{V}$ to axiom $\text{V}^*$, the resulting system $\text{V}_{\text{imp}}$ recovers $\text{FA}$ and $\text{PA}^2$ in a way that parallels Frege’s. This advantage is due to the fact that $\text{V}_{\text{imp}}$ allows for any formula not containing free plural variables to appear within the extension-terms governed by $\text{V}^*$, thus delivering, first and foremost, a Fregean notion of number by the definition of $\#$, which is necessary to deliver $\text{FA}$ and Frege’s Theorem.\(^{35}\)

At the same time, $\text{V}_{\text{imp}}$ is also a consistent extension of the system $\text{PE}$ in [Ferreira 2018]. Though likely the two systems are mathematically equivalent, it was argued that $\text{V}_{\text{imp}}$ has some nice advantages over $\text{PE}$. First of all, $\text{V}_{\text{imp}}$ requires a somewhat weaker logico-mathematical machinery to carry out its main goal: $\text{V}_{\text{imp}}$ requires [Ferreira 2018]’s weak reducibility to prove the Successor Axiom, but on the basis of more liberal restrictions than $\text{PE}$ it can interpret $\text{FA}$ without further ado. Meanwhile, $\text{PE}$ necessarily relies upon not only weak reducibility to prove the Successor Axiom, but also on finite reducibility, a stronger result than the former, in order to interpret $\text{FA}$ to begin with. By its consistency proof, $\text{V}_{\text{imp}}$ shows that the restrictions that prevent $\text{PE}$ from interpreting $\text{FA}$ without appealing to finite reducibility can be lifted. Secondly, on the basis of those same restrictions, unlike $\text{V}_{\text{imp}}$, $\text{PE}$ cannot collect the totality of finite cardinals in the extension of the concept natural number, because of the irreducible impredicativity of this latter. This is not to say that $\text{V}_{\text{imp}}$ is stronger than $\text{PE}$, but at least $\text{V}_{\text{imp}}$ might provide a starting point to recover larger fragments of set theory.

NOTES

1. See, for instance, the famous debate between Boolos and Dummett on the cause of the inconsistency in Frege’s Grundgesetze. Dummett ascribes the inconsistency to the underlying second-order logic, in particular to the indefinite extensibility of the very notion of concept. On the other hand, Boolos ascribes the contradiction to the violation of Cantor’s theorem embodied in the one-to-one correspondence Frege’s BLV poses between concepts and objects. But see [Paseau 2015] in this respect.

2. See [Burgess 2005, § 2.6], [Ferreira & Wehmeier 2002], [Heck 1996], and [Wehmeier 1999]. Famously, Robinson’s Q lacks a (first-order) induction principle, i.e., \( \forall x (x \rightarrow x) \rightarrow \forall x \forall y (x = y) \). In the above consistent subsystems of Frege’s Grundgesetze, the concept being a natural number cannot be defined in such a way that any interesting class of inductions can be proved, because of its irreducible impredicativity—e.g., this is pointed out by [Heck 1996] with regards to their predicative subsystem of Grundgesetze. Also, it has to be mentioned that the extension operator governed by (fragments of) BLV can either be functional and take second-order variables as arguments, or variable-binding and take first-order variables as arguments. For instance, [Ganea 2007] proves the equi-interpretability of the predicative fragment of BLV with a functional operator with Robinson’s Q. See also [Cruz-Filipe & Ferreira 2015] for a thorough discussion of these issues.

3. In [Boccuni 2010] a different notation is used for plural formulae, i.e., \( \chi \eta X \), meaning “\( \chi \) is one of the \( x \)’s”. In the present article, I will rephrase [Boccuni 2010]’s plural notation in the standard notation, i.e., \( x \prec x \). Other things being equal, these two notations imply neither a deductive nor a semantic difference.

4. See [Boccuni 2010] and [Boolos 1985] for considerations supporting the claim that PRC is indeed predicative, even though it allows for bound plural variables on its right-hand side. Also, the aim of this article is merely technical, so I will not delve into philosophical issues. Still, for philosophical considerations on the difference between plural and second-order quantification, see [Boccuni 2010].

5. In P, [Ferreira 2018], and in the system presented in this article, concepts are the values of second-order variables.

6. In [Ferreira 2018], the system PE is presented, which consists of two rounds of second-order variables \( \mathcal{L}, \mathcal{G}, \ldots \) and \( F, G, H, \ldots \) respectively governed by an impredicative comprehension axiom \( \exists! \forall x (x \leftrightarrow \varphi x) \), where \( \varphi \) is unrestricted; a predicative comprehension axiom \( \exists! \forall x (f x \leftrightarrow \varphi x) \) where \( \varphi \) contains neither bound predicative
variables nor impredicative variables at all; and a formulation of $\text{BLV}$, i.e., 
\[ \hat{x}.Ax \leftrightarrow \forall x(Ax \leftrightarrow Bx) \] 
with a variable-binding operator $\hat{x}$, where $A$ and $B$ contain no 
impredicative variables at all, but can contain predicative variables both free and 
bond. PE is consistent and strong enough to recover FA. More remarks on PE will be 
provided later on.

7. The same considerations mentioned in fn. 4 above apply also to $\text{PRC}$ in $V_{\text{imp}}$.

8. Modulo a translation of PE’s second-orderly impredicative fragment into $V_{\text{imp}}$’s plural 
fragment. Notice that both in $V_{\text{imp}}$ and in [Boccuni 2010], as also in [Ferreira 2018] and 
[Heck 1996], the extension operator is variable-binding. Both in $V_{\text{imp}}$ and in [Ferreira 
2018], this is crucial, since complex formulæ are needed in the scope of the extension 
operator for recovering FA.

9. Also in [Ferreira 2018] there is no one-to-one correspondence between (predicative, 
let alone impredicative) concepts and extensions, and FA is recovered.

10. See [Tennant 2017] on these and other issues connected with logicism.

11. Recall that in $V_{\text{imp}}$, just like in PG, bound second-order variables are not allowed on 
the right-hand side of $\text{PRC}$, so that also formulæ containing extension-terms with bound 
second-order variables are not allowed on the right-hand side of $\text{PRC}$ in either theories. 
Also, it goes without saying that extension-terms can contain free and bound first-
order variables.

12. As mentioned, extension-terms can contain free first-order variables. The values of 
these are provided by [Boccuni 2007] in line with [Heck 1996], namely by substituting 
with numerals free first-order variables other than the designated first-order variable.

13. Instances containing free second-order variables and bound plural variables are 
proved to hold by [Boccuni 2011]’s construction.

14. Where $x$ is their sole free variable.

15. The proof goes analogously if $\{x : Bx\}$ precedes $\{x : Ax\}$ in the $\omega \times \omega$-sequence.

16. Since PE is a subsystem of $V_{\text{imp}}$, the consistency of $V_{\text{imp}}$ implies that in PE the ban on 
bound impredicative second-order variables in PE’s predicative second-order 
comprehension axiom and PE’s $\text{BLV}$ can be consistently lifted. Analogously as for $V$ in PG.

17. The Weak Reducibility Theorem in [Ferreira 2018] states that, if $x$ is a natural 
number, there is a (predicative) concept that is co-extensive with the formula $y \leq x$, 
where $s$ is defined impredicatively. This theorem is implied by a Finite Reducibility 
Theorem in PE, which states that every finite impredicative concept (relation) is co-
extensive with a (finite) predicative concept (relation). Since PE is a subtheory of $V_{\text{imp}}$, 
these theorems follow in $V_{\text{imp}}$ as well, though in a plural formulation.

18. Given its formulation, in $V_{\text{imp}}$, HP is restricted to $\text{PRC}$-definable concepts. We’ll see this 
poses some issues as for the proof of Frege’s Theorem, which, nevertheless, can be 
easily overcome. See § 3.2.

19. Boolos’ plural logic is monadic, so as it stands it cannot be used to define the 
equinumerosity relation. This issue can be easily circumvented by defining the notions 
of singleton, unordered pair, and (Wiener-Kuratowski) ordered pair in $V_{\text{imp}}$, 
\[ \{x\} \equiv \{y : x = y\}; \{x,y\} = \{z : z = x \lor z = y\}, \text{and } (x,y) = \{(x),(x,y)\}, \] 
respectively. On the basis of the definition of ordered pairs, the set of the well-formed plural formulæ of the language of
\(v_{imp}\) contains formulæ of the form \((x,y) xx\), so that also the plural fragment of the language of \(v_{imp}\) is polyadic.

20. For the sake of clarity, I will use the following notational convention: if a complex PRC-permissible formula, e.g., \(x \neq x \land \exists xx(x xx)\), is co-extensive with a concept that has a number, I will construe the corresponding number-term as \("[x,x \neq x \land \exists xx(x xx)]\", namely the number of all individuals \(x\) such that \(x \neq x \land \exists xx(x xx)\).

21. The Successor Axiom.

23. This can be accomplished by a definition of Fregean finitude, which mirrors Frege’s definition as in [Heck 2012, § 8.1], according to which a plurality \(xx\) is finite if, and only if, “\(x\) belongs to the \(xx\)-series running from \(a\) to \(b\)”, i.e., \(xx\) is functional, and is such that \((b,b) xx’, (a,x) xx’, and (x,b) xx’\).

24. In order to prove the Successor Axiom, [Ferreira 2018] proves a stronger theorem, i.e., \(\forall(Nx \rightarrow \exists f(\forall u(\forall x u \equiv x) \land S(x, #f)))\), where \(S\) is the Successor relation, by taking advantage of weak reducibility.

25. The right-hand side formula is a valid instance of PLC.

26. Recall that, by definition, \(s\)-formulæ stand for \(pp\’\)-formulæ. That \(pp\’\), while appearing to be a free plural variable, is contained in \(\#\)-terms is not problematic: in fact, every single instance of it can be substituted by its defining formula, which contains no free plural variables at all. See also below.

27. This can be easily proved by induction on the basis of basic facts about the ancestral, i.e., for any \(xx\), \(yy\) \((a,b) xx’ \land \forall x, y (x yy \land (x,y) xx \rightarrow y yy) \land \forall x ((a,x) xx \rightarrow x yy) \rightarrow b yy\). See [Heck 2012, § 6.6.2, fn. 29].

28. Lemma Concerning Zero: \(\#F = 0 \rightarrow \exists x Fx\). See [Zalta 2017].

29. By HP, it suffices to show \([zz \leq x] = [zz \leq y \land z \neq y]\), on the basis of the definition of \(s\) and weak reducibility. Since it’s a fact about equinumerosity that co-extensive conditions are equinumerous, we have that \(\forall z (z \leq x) \equiv \forall z (z \leq y \land z \neq y)\), which, by the definition of \(s\), is provable from facts about the weak ancestral. See [Zalta 2017]. Notice, though, that the proof of the Lemma on the Weak Predecessor in [Zalta 2017] follows from a further lemma, i.e., the lemma that no number strongly precedes (i.e., \(pp\’\)) itself: \(\forall x (x \in \mathbb{N} \rightarrow (x,x pp’))\).

30. Notice that the proof of the Lemma on Successors, in order to introduce the plurality \(qq\), requires an instance of PLC containing bound second-order variables in the condition \((y, \#[z,z \equiv y]) pp\) once \(#, s\) and \(pp\) are unfolded. As pointed out by [Heck 1996] and [Linnebo 2004], in order to follow Frege’s proof of the Successor Axiom via his definitions, we need to apply a fragment of impredicative reasoning. This, along with the requirement that \(pp\) and \(\mathbb{N}\) should be plugged in the principle of Mathematical Induction in order to recover full \(P\mathcal{L}\), are the passages of the proof of Frege’s Theorem where impredicative reasoning is necessary, whether plural or second-order.

32. Though, it is likely that \(v_{imp}\) and \(v_{imp}\) have the same mathematical strength. This claim would require a proof that goes beyond the aim of this article, so I shall just state it as a (reasonable) conjecture.
33. Where

\[ \text{Her}(xx, \exists F \exists u (F u \land x = \# F \land 0 = \# [z.F z \land z \neq u])) \]

\[ \text{Her}(xx, \exists F \exists u (F u \land x = \# F \land 0 = \# [z.F z \land z \neq u])) \rightarrow (0 xx \rightarrow x xx). \]

34. For instance, we might consider adding further consistent formulations of BLV to \( V_{\text{imp}} \) in order to recover real analysis starting from the extension of all natural numbers—see, e.g., [Hale 2005] or [Panza 2016]. But see also [Boccuni & Panza 2021] for a critical view of this strategy, and an alternative.

### ABSTRACTS

In [Boccuni 2010], a predicative fragment of Frege’s BLV augmented with Boolos’ unrestricted plural quantification is shown to interpret PA\(^2\). The main disadvantage of that axiomatisation is that it does not recover Frege Arithmetic FA because of the restrictions imposed on the axioms. The aim of the present article is to show how [Boccuni 2010] can be consistently extended so as to interpret FA and consequently PA\(^2\) in a way that parallels Frege’s. In that way, the presented system will be compared with the system PE in [Ferreira 2018] and some relevant differences between the two will be highlighted.

Dans [Boccuni 2010], un fragment prédicatif du BLV de Frege augmenté de la quantification plurielle illimitée de Boolos interprète PA\(^2\). Le principal inconvénient de cette axiomatisation est qu’elle ne récupère pas Frege Arithmetic (FA), en raison des restrictions imposées aux axiomes. Le but du présent article est de montrer comment [Boccuni 2010] peut être étendu de manière cohérente afin d’interpréter FA et par conséquent PA\(^2\) d’une manière qui soit parallèle à celle de Frege. Ce faisant, le système présenté sera mis en comparaison avec le système PE dans [Ferreira 2018] et quelques différences pertinentes entre les deux seront mises en évidence.
